### Abstract

A work on the *Celtis tournefortii* subsp. *aetnensis* vegetation, endemic species located in disjointed sites in the Sicilian inland, is here presented. It forms microwoods with a relict character established on scree and detrital coverages, on a variety of lithological substrates (volcanics, limestones, quartzarenites). Based on the phytosociological analysis carried out in the territory, these vegetation aspects are framed in the alliance *Oleo-Ceratoniion*, within which a new association (*Pistacio terebinthi-Celtidetum aetnensis*) is described, in turn diversified in the following subassociations: a) *typicum* subass. nova, on detrital calcareous cones of the north-western part of Sicily, in the Palermo province (Rocca Busambra, Pizzo Castelluzzo and northern slopes of Pizzo Telegrafo); b) *phlomidetosum fruticosae* subass. nova, typical of carbonate megabreccias, on the most xeric southern slopes of Pizzo Telegrafo (Caltabellotta territory, Agrigento province); c) *artemisetosum arborescentis* subass. nova, typical of quartzarenitic outcrops on the Nebrodi Mts. inland (Cesarò territory, Messina province); d) *rhamnetosum alaterni* subass. nova, widespread on cracked lava flows of the western side of Mount Etna (Catania province).

Keywords: biodiversity, *Celtis tournefortii* Lam. subsp. *aetnensis* (Tornab.), Mediterranean vegetation, phytosociology, *Pistacio-Rhamnetalia alaterni*, Sicily, syntaxonomy.

### Introduction

In the genus *Celtis* [fam. *Celtidaceae* (ex *Ulmaceae-Celtidoideae*; Elias, 1970; Ueda *et al.*, 1997) or *Canabaceae* (Sytsma *et al.*, 2002; Whittemore, 2005)], *Celtis tournefortii* Lam. represents one of the three species known for the European territory, together with *C. australis* L. and *C. plachoniana* K.I. Chr. (= *C. glabrata* Steven ex Planch., not Sprengel). It is widely distributed along the southern margin of the European Region, however with quite sparse and fragmentary stations, among Crimea, Iran and Anatolia, as well as on the Crete Island, the Balkan Peninsula – as far north as in Bulgaria (Zielinski *et al.*, 2012), Macedonia (Micevski, 1993) and the coasts of Bosnia and Herzegovina (Jalas & Suominen, 1976) – up to Sicily (Jalas & Suominen, 1976; Tutin *et al.*, 1964-80; Poli *et al.*, 1974, 1981; De Castro & Maugeri, 2006; Giardina *et al.*, 2007), where it reaches its extreme western limit and to which the present paper refers.

Therefore, these populations have a particular phyto-geographical value and they are at the centre of taxonomic debates among various authors, tending in part to characterize one or more taxa endemic to the island territory (Strobl, 1880; Lojacono Pojero, 1888-1909; Raimondo & Schicchi, in Giardina *et al.*, 2007). On this basis – in the absence of precise comparative studies with a morpho-anatomical and physiological character – they are here referred to *Celtis tournefortii* Lam. subsp. *aetnensis* (Tornab.) Raimondo & Schicchi

(in Giardina *et al.*, 2007) [= *C. tournefortii* var. *aetnensis* Tornab.; *C. aetnensis* (Tornab.) Strobl; included *C. betulina* Lojac. and *Celtis asperrima* Lojac.]

The plant is a small tree, 4-6 (8) high, spring-flowering and autumn-fruiting, tending to form xeric-thermophilous communities, though it is a winter-deciduous species; this habitus, in fact, is not common among the Mediterranean woody species of xeric environments, more typically represented by evergreen sclerophyllous or summer-deciduous species. In Sicily the entity has a main subrange located on the volcanics of the western part of Mt. Etna (Poli *et al.*, 1974, 1981; Brullo & Marcenò, 1985; Brullo *et al.*, 2009), with other relict and disjointed nuclei distributed westward, on different lithological substrates. These latter sites affect the inner side of the Nebrodi Mts. (Giardina, 1990), the Sicilian hinterland south of the Madonie Mts. (Schicchi & Marino, 2011), the southern slope of Rocca Busambra (Lojacono Pojero, 1904; Troia, 1997) and limited biotopes of the Sicani Mts., in particular Pizzo Castelluzzo (Troia & Ilardi, 2002; Marino & Castellano, 2006), and the complex of Pizzo Telegrafo, at Contrada Cavallaro (Marcenò *et al.*, 1995, 2002) and among the S. Biagio, Cava Grande, Inchiuse, Utine, Cavallaro, Cannerie and Catusa districts (Gianguzzi *et al.*, 2014), in the Sambuca di Sicilia (Palermo province) and Caltabellotta territories (Agrigento province).

Under the phytosociological aspect, *Celtis tournefortii* subsp. *aetnensis* has been indicated so far as a more or less gregarious element in the following commu-

Corresponding author: Lorenzo Gianguzzi. Department of Agricultural and Forest Sciences, University of Palermo, Via Archirafi 38 - I-90123 Palermo, Italy, e-mail: lorenzo.gianguzzi@unipa.it

nities ascribed to the class *Quercetea ilicis*, though to different orders: a) *Quercus ilex* woods in the Etna area [*Celtido-Querchetum ilicis* n.n. (sub *C. aetnensis*) (Poli *et al.*, 1973, 1981)]; b) *Quercus virgiliiana* woods in the western side of Mt. Etna [*Celtido aetnensis-Querchetum virgiliiana* Brullo & Marcenò, 1985 (sub *C. aetnensis*) (Brullo *et al.*, 2009)]; c) *Euphorbia dendroides* maquis at Caltabellotta, in the Agrigento province [*Oleo-Euphorbietum dendroidis* Trinajstić (1973) 1984 subass. *celtidetosum tournefortii* Marcenò *et al.* 2002 (sub *C. tournefortii*) (Marcenò *et al.*, 1995, 2002)].

The present work takes the cue from a recent finding of some vegetation nuclei dominated by the species located on Pizzo Telegrafo, in the southern part of the Sicani Mts. (Gianguzzi *et al.*, 2014), where the species constitute interesting microwoods with a relict character, belonging to a pioneer vegetation series typical of screes of carbonate nature. The paper deals with the phytosociological role of the species in the various vegetation aspects located in Sicily, considering that the aforecited coenoses had been in turn ascribed to distinct orders of the class *Quercetea ilicis*.

## Materials and Methods

The research started in 2008, after the finding of some microwoody nuclei of the species pinpointed in the southern part of the Sicani Mts., then extending the survey to the other known stations in Sicily.

### Taxonomical and chorological analysis

For the determination of the species listed in the text, reference was made to the floras of Pignatti (1982) and Fiori (1923-29). The taxonomical nomenclature mainly follows Giardina *et al.* (2007) and Tutin *et al.* (1964-1980, 1993), except for *C. aetnensis* (Tornab.) Strobl., which refers to De Castro & Maugeri (2006). The ex-siccata collected during the field research are kept at the Department of Agricultural and Forest Sciences of the University of Palermo.

The general distribution map of *Celtis tournefortii*

subsp. *aetnensis* in Sicily (Fig. 1) was realized on the basis of unpublished data collected during the present survey, in addition to references reported in the bibliography for Etna (Poli *et al.*, 1974, 1981; Brullo & Marcenò, 1985; Brullo *et al.*, 2009), Nebrodi Mts. (Giardina, 1990), Gangi at Portella d'Argento and Cozzo Ficilino (Schicchi & Marino, 2011), Rocca Busambra (Lojacono Poiero, 1904; Troia, 1997), Pizzo Castelluzzo (Troia & Ilardi, 2002; Marino *et al.*, 2005; Marino & Castellano, 2006) and Caltabellotta (Marcenò *et al.*, 1995, 2002).

### Description of the study area

For the ecological framework of the sites, several bibliographical contributions of geolithological (Mascole, 1974; Di Stefano & Vitale, 1992; Romano, 1999; Lentini *et al.*, 2000) and bioclimatic nature (Gianguzzi, 1999; Gianguzzi *et al.*, 2000, 2002; Gianguzzi & La Mantia, 2004; Drago, 2005) were consulted.

The distribution of *Celtis tournefortii* subsp. *aetnensis* in Sicily was localized in six separate sites (Fig. 1) – each of them with one or more stations –, whose main stational characteristics, summarized in Tab. 1, are reported below.

1) Carbonate complex of Pizzo Telegrafo (Bisacquino-Caltabellotta).

These microwoody nuclei – many of them previously unpublished and located on two separate sides of Pizzo Telegrafo (952 m a.s.l.) – cover a total area of well over 50 hectares. The species is spread out well beyond the biotope of Contrada Cavallaro already reported by Marcenò *et al.* (1995), and whose population was estimated to be only 300 individuals (Schicchi & Marino, 2011). In the northern slopes they are found on the various screes that characterize the area, at altitudes between 380 m and 785 m a.s.l. A further population is found along the southern slopes, affecting a very expansive area. These latter nuclei establish both on screes and on debris coverages in karst depressions, between 480 m and 782 m a.s.l. Under the geolitholo-

Tab. 1 - Characteristics of the surveyed sites, with mean altitude, exposure, lithological substrata and bioclimate.

Locality (municipality, administrative province)	Altitude (m)	Exposure	Substrate	Bioclimate
1) Pizzo Telegrafo (Palermo and Agrigento provinces)	380-790	various	Calcareous megabreccias and marly debris	Upper mesomediterranean lower subhumid
2) Pizzo Castelluzzo (S. Stefano Quisquina, Palermo)	810-960	W/SW	Limestone	Upper mesomediterranean lower subhumid
3) Rocca Busambra (Monreale and Corleone, Palermo)	800-1100	S/SW	Limestone-dolomite	Upper mesomediterranean lower subhumid
4) Sicilian inland (Gangi, Palermo)	900-1000	S	Limestone	Upper mesomediterranean lower subhumid
5) Nebrodi district (Cesarò, Messina)	680-1260	SW	Quartzarenites	Mesomediterranean upper dry/ lower subhumid
6) South-western side of Mount Etna (Catania province)	380-1100	S, W	Basaltic lavas	Thermo-mesomediterranean upper dry/ lower subhumid

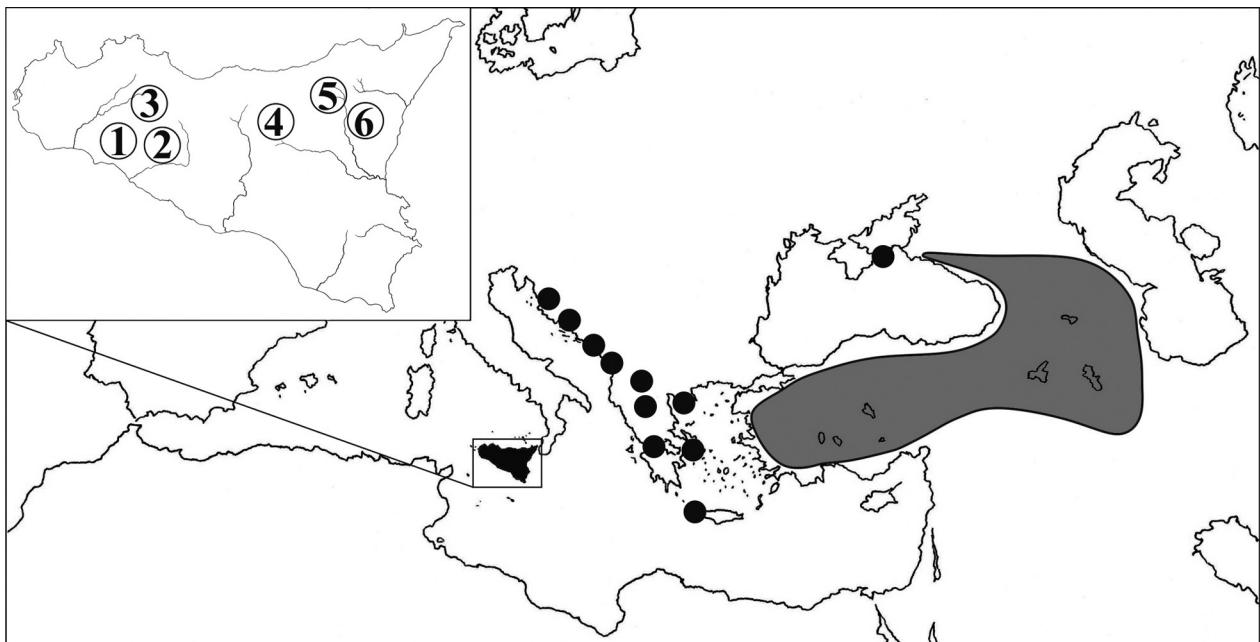

Fig. 1 - Distribution map of *Celtis tournefortii* s.l. and, in the detail, location of the sites in Sicily, referred to the subsp. *aetnensis*: (1) Pizzo Telegrafo (Bisacquino, Caltabellotta); (2) Pizzo Castelluzzo (S. Stefano Quisquina); (3) Rocca Busambra (Corleone); (4) Portella Argento (Gangi); (5) Nebrodi Mts. inland (Cesarò); (6) Mount Etna.

gical aspect, they mainly are calcareous megabreccias and marly debris referred to the Mount Magaggiaro-Pizzo Telegrafo Unit (Di Stefano & Vitale, 1992). The area lies within the SCI ITA 040006 "Complesso Monte Telegrafo e Rocca Ficuzza" and the SPA ITA 020048 "Monti Sicani, Rocca Busambra e Bosco della Ficuzza".

### 2) Pizzo Castelluzzo (S. Stefano Quisquina).

Small site located along the southern slopes of Pizzo Castelluzzo (Ilardi & Troia, 2002; Marino & Castellano, 2006; Schicchi & Marino, 2011); the species is found with sparse nuclei, spread over an area of about 2 hectares, between 810 and 960 m a.s.l. The habitat is represented by a scree relatively sheltered from cold winds. Sporadic other presences of the species on the sidelines of the rocky outcrops extending up to the summit. Under the geological aspect, they are carbonate and silicate-carbonate substrates of the Sicani Units, sometimes with cherty marls and limestones (Di Stefano & Vitale, 1992).

### 3) Southern slopes of Rocca Busambra (Monreale and Corleone).

The site falls within the Nature Reserve "Bosco Ficuzza, Rocca Busambra, Bosco del Cappelliere e Gorgo del Drago", as well as the SCI ITA 020008 "Rocca Busambra e Rocche di Rao" and the SPA ITA 020048 "Monti Sicani, Rocca Busambra e Bosco della Ficuzza". These are isolated nuclei distributed over an area of about 1-2 hectares, between 800 and about 1100 (1200) m a.s.l. (Troia, 1997). They are calcareous-

dolomitic substrates (Mascole, 1974), within which the microwoods mainly establish on detrital cones pedologically poor and somewhat xeric.

### 4) Sicilian inland (Gangi, Palermo province).

Small site located close to the evaporitic outcrops of the Sicilian inland, beyond the extreme southern limit of Madonie Mts., on detrital coverages of carbonate nature (Schicchi & Marino, 2011).

### 5) Quartzarenitic complex of the southern side of the Nebrodi Mts. (Cesarò, Messina province).

The site, located in the southern and innermost part of the Nebrodi Mts., consists of four distinct and among them isolated stations, on a total area of about 2 hectares. Two of them are located along the southern slopes of the quartzarenitic spikes, respectively, of Rocca Rapiti (1335 m) and Rocca Nadore (1038 m), at altitudes of about 1248 m and 1005 m a.s.l. (Giardina, 1990). The third station is located in Contrada Mercadante (Giardina, 1990), between 850 m and 875 m a.s.l. The fourth station falls within the SCI ITA 070026 "Forre Laviche del Simeto", located on outcrops in the north-east of the Serravalle River (Poli *et al.*, 1974). Under the geological aspect, the coenosis establishes on isolated quartzarenitic banks, emerging within the brown clays of the Numidian Flysch dominating the entire area, these latter unsuitable for the establishment of the species. These various substrates are referred to the Nicosia Unit of the Sicilide Complex, sometimes with the presence at the top of marly limestones and marls with cherty strips (Lentini *et al.*, 2000).

### 6) South-western side of Mount Etna.

This is the main subrange of the species, whose northern limit is placed between the towns of Bronte and Maletto, extending to south-east up to the towns of Nicolosi and Belpasso, particularly along the lava flow of 1910 (Poli *et al.*, 1974; Romano, 1999). Under the conservation aspect, the subrange affects the areas of the Etna Regional Park, of the SCI ITA 070023 "Monte Minardo", of the SCI/SPA ITA070017 "Sciare di Roccazzzo della Bandiera" and the SCI/SPA ITA070018 "Piano dei Grilli".

### **Phytosociological, synecological and syndinamical analyses**

The study of the plant communities was carried out based on 32 unpublished phytosociological relevés, in addition to other four already published by Marcenò *et al.* (2002), in order to characterize the typological variability of the phytocoenoses in relation to the ecological parameters. The vegetation study was carried out according to the Zurich-Montpellier School methodology, adopting the abundance-dominance indices proposed by Braun-Blanquet (1964), updated on the basis of the latest acquisitions (Géhu & Rivas-Martínez, 1981; Biondi, 1994, 2011; Biondi *et al.*, 2004, 2011; Rivas-Martínez, 2005; Blasi *et al.*, 2011; Géhu, 2011; Pott, 2011). On the basis of the total set of phytosociological relevés a 36 relevés × 82 species matrix was obtained, in turn subjected to cluster analysis (UPGMA) based on Euclidean distance measures performed with the software Syntax 2000 (Podani, 2001).

For the syntaxonomical treatment, we followed the criteria of the International Code of Phytosociological Nomenclature (Weber *et al.*, 2000) and the scheme proposed by Rivas-Martínez *et al.* (2001, 2002) up to the alliance, apart from some updating listed in the bibliography. The synecological analysis was performed according to the methodological principles of Syn-phytosociology (Géhu & Rivas-Martínez, 1981). The references to sigmeta refer to the Carta delle serie di vegetazione d'Italia (Bazan *et al.*, 2010; Blasi, 2010) and any other studies reported in the text.

### Results

#### **Phytosociological and synecological analysis**

Multivariate analysis performed on the phytosociological relevés reported in Tab. 2, allowed to obtain the dendrogram reported in Fig. 2. In the graph four clusters, corresponding to as many subassociations of the same association, are highlighted, all well differentiated from the floristic and ecological point of view, and which are described below.

**PISTACIO TEREBINTHI-CELTIDETUM AETNENSIS ass. nova** hoc loco (holotypus rel. 12, Tab. 2)

**Characteristic/Differential species:** *Celtis aetnensis* (dom.), *Pistacia terebinthus*.

**Structure and ecology:** Microwoody community dominated by *Celtis aetnensis*, associated with *Pistacia terebinthus* – other winter deciduous which shapes the physiognomy of the coenosis –, as well as various lianas elements of the Mediterranean maquis (*Clematis cirrhosa*, *Rubia peregrina*, *Smilax aspera*, *Asparagus acutifolius*, *Lonicera etrusca*) and other thermophilous sclerophytes (*Asparagus albus*, *Euphorbia characias*, *Ruta chalepensis*, *Olea europaea* var. *sylvestris*, ecc.). The coenosis constitutes vegetation aspects with a generally linear growth, 3-5 (8) m high, established on clastic material located along steep slopes, watersheds, karst depressions or at the base of cliffs of various nature, as well as on cracked lava flows; it is found at altitudes ranging from 380 m (Sicani Mts., Pizzo Telegafo) to over 1000 m a.s.l. (Rocca Busambra, Rocca Rapiti, Rocca Nadore, Mt. Etna). On calcareous-dolomitic substrates it generally tends to circumscribe the outer and most stabilised margins of screes, placed close to rocky cliffs or steep slopes; they mainly are active cones, constantly fed by new contributions of detrital material originated from landslides and erosion processes. It can also be found on the terraces between cultivated fields (Mt. Etna), as well as among the heaps of stones accumulated over time by the man between the arable crops – locally known as "chirchiari" – as well as on rocky ridges, isolated outcrops or more or less fissured lava flows, in areas little exposed to the cold northerly winds (Fig. 3).

**Syndinamism:** These microwoods represent the most developed aspect of the "submountain and hilly Sicilian, detrital, indifferent edaphic, thermo-mesomediterranean subhumid series of the Etna hackberry" (*Pi-*

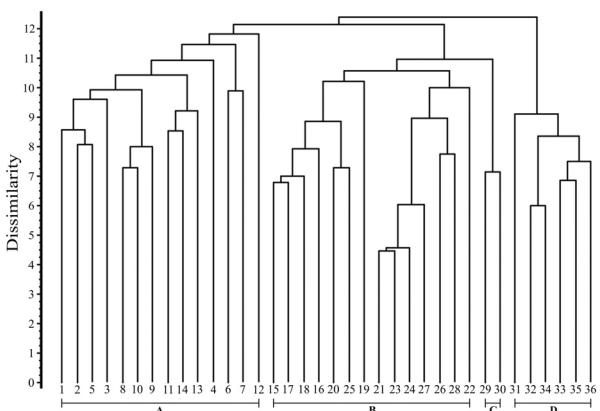

Fig. 2 - Dendrogram obtained through the synoptic comparison among the coenoses reported in Tab. 2 (cluster analysis, UPGMA). *Pistacio terebinthi-Celtidetum aetnensis* ass. nova: A) *typicum* subass. nova (rel. 1-14); B) *phlomidetosum fruticosae* subass. nova (rel. 15-28); C) *artemisietosum arborescentis* subass. nova (rel. 29-30); D) *rhamnetosum alterni* subass. nova (rel. 31-36).

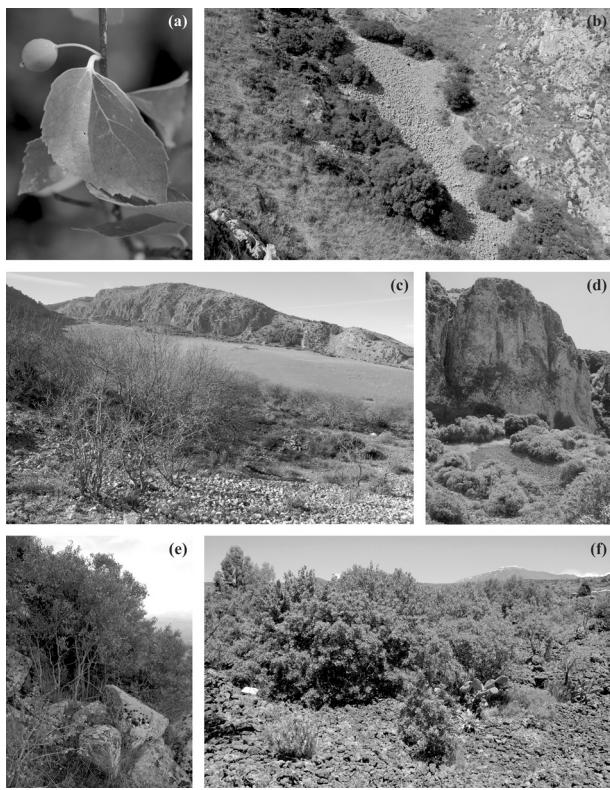

Fig. 3 - Twig with fruit of *Celtis tournefortii* subsp. *aetnensis* (a) and aspects of residual microwoods of the *Pistacio terebinthi-Celtidetum aetnensis* ass. nova, diversified in the following subassociations: - *typicum* subass. nova, on detrital cones of calcareous nature, on the northern slopes of Pizzo Telegrafo (Sicani Mts.), at Cozzo Pozzillo (b) and, in wintry habitus, in contrada S. Biagio (c); - *phlomidetosum fruticosae* subass. nova, on the most xeric screes of the southern slopes of Pizzo Telegrafo (d); - *artemisietosum arborescentis* subass. nova, among the quartzarenitic blocks at Rocca Rapiti (e), in Cesaro territory; - *rhamnetosum alaterni* subass. nova, on the cracked lava flows of the western slope of Mount Etna (f), here at Adrano.

*stacio terebinthi-Celtido aetnensis* sigmetum). It is an edaphophilous series with a glareicolous and pioneer character, whose peculiarity is inherent in the habitat dynamics itself, greatly influenced by the continuous reworking of the substrate due to continuous intake caused by erosion and landslides, as well as by the peculiar microclimatic conditions, with remarkable daily and yearly temperature range. Inwards of the debris cone, the sygmetum normally finds catenal contacts with shrubby aspects of the detrital microgeoseries, whereas outwards – where typically the debris of greater size locate – it finds catenal contacts with aspects of further *Quercus ilex* woody series. Upwards instead it puts itself into contact with the geoseries tied to the rupicolous environments of the rocky cliffs (Fig. 4).

**Bioclimate:** Upper thermomediterranean/mesomediterranean, with upper dry/subhumid ombrotype.

*PISTACIO TEREBINTHI-CELTIDETUM AETNENSIS TYPICUM* subass. nova hoc loco (holotypus rel. 12, Tab. 2)

**Table:** 2, relevés 1-14.

**Differential species:** *Ruta chalepensis*, *Smyrnium olusatrum*, *Prunus spinosa*.

**Substrate:** Detrital cones placed close to shady cliffs of carbonate nature.

**Bioclimate:** Upper mesomediterranean lower subhumid.

**Syndinamism:** Microwoods 3-4.5 (6) m high, tied to detrital series, in catenal contact inwards of the scree with the pioneer shrub community with *Smilax aspera*, and outwards with the series of the holm oak community (*Aceri campestris-Querco ilicis* sigmetum), representative of the most advanced and stabilized aspects.

**Distribution:** Sicani Mts. and Sicilian inland, in Bisacquino territory (northern slopes of Pizzo Telegrafo, in Contrada S. Biagio), S. Stefano Quisquina (Pizzo Castelluzzo), Corleone (southern slopes of Rocca Busambra) and Gangi (Cozzo Ficilino).

*PHLOMIDETOSUM FRUTICOSAE* subass. nova hoc loco (holotypus rel. 25, Tab. 2)

**Syntaxonomical notes:** Marcenò et al. (2002) describe for the Caltabellotta area (south-western Sicily) the *Oleo-Euphorbietum dendroidis* Trinajstić (1974) 1984 subass. *celtidetosum tournefortii* Marcenò, Romano & Ottonello 2002, on the basis of a synoptic table

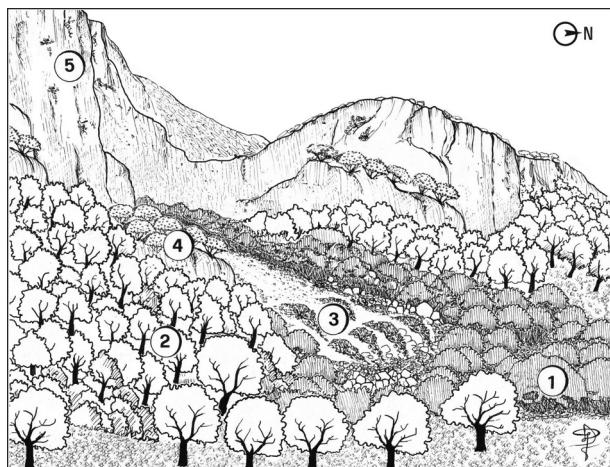

Fig. 4 - Schematic transect of the plant landscape of Pizzo Telegrafo (Sicani Mts.), in Contrada S. Biagio: (1) *Celtis tournefortii* subsp. *aetnensis* microwoods (*Pistacio terebinthi-Celtidetum aetnensis* ass. nova *typicum* subass. nova); (2) *Quercus ilex* subsp. *ilex* wood (*Aceri campestris-Quercetum ilicis*); (3) shrubby aspects of detrital areas (*Smilax aspera* community); (4) *Euphorbia dendroides* maquis (*Euphorbietum dendroidis*); (5) chasmophytic community (*Dianthion rupicolae*).

Tab. 2 - *Pistacia terebinthi*-*Celtidetum aetennensis* ass. nova: A) *typicum* subass. nova (rel. 1-14); B) *phlomidetosum fruticosae* subass. nova (rel. 15-28); C) *artemisietsorum arborescensit* subass. nova (rel. 29-30); D) *rhamnetosum alaternii* subass. nova (rel. 31-36). Location and data of relevés are reported in Appendix 1, the sporadic species in Appendix 2.

which reports six relevés (Tab. 1, rel. 12-17, holotypus rel. 16). However, this includes two different vegetation aspects, since the relevés 12 and 16 are ascribable to the *Oleo-Euphorbietum* s.l. maquis, whereas the others relevés (13, 14, 15 and 17) concern *Celtis tournefortii* subsp. *aetnensis* (sub *Celtis tournefortii*) microwoods, considered the degree of coverage of this species (4 or 5). Given the frequency of *Phlomis fruticosa*, also these relevés are to be attributed to the *Pistacio terebinthi-Celtidetum aetnensis phlomidetosum fruticosae* subass. nova.

**Pseudonym:** *Oleo-Euphorbietum dendroidis* Trinajstić (1974) 1984 subass. *celtidetosum tournefortii* Marcenò, Ottonello & Romano 2002 p.p. (sensu Marcenò *et al.*, 2002: rel. 13-15 and 17, Tab. 1); *Euphorbietum dendroidis* Guinochet in Guinochet & Drouineau 1944 subass. *celtidetosum tournefortii* (Marcenò, Ottonello & Romano 2002) Brullo, Gianguzzi, La Mantia & Siracusa (sensu Brullo *et al.*, 2009).

**Table:** 2, relevés 15-28.

#### **Differential species: *Phlomis fruticosa***

**Substrate:** Detrital cones placed close to shady cliffs of carbonate nature.

**Bioclimate:** Upper mesomediterranean lower subumid.

**Syndinamism:** Microwoods (3) 4-6 (8) m high, tied to 1) detrital cones on very steep slopes, with prevailing south exposure; 2) debris coverages on karst depressions; 3) heaps of stones at the edge of ex-cultivated fields. Inwards of the screes, the coenosis is found in catenal contact with pioneer shrubby aspects, whereas outwards it can be found in contact with: a) the *Olea europaea* var. *sylvestris* and *Euphorbia dendroides* maquis series, on xerophilous rocky outcrops (*Euphorbia dendroidis* sigmetum); b) the holm oak series (*Rhamno alaterni-Querco ilicis* sigmetum), in cooler and pedologically evolved areas. On the heaps of stones located in the depressions of Pizzo Telegrafo, the coenosis is found in contact with the *Quercus virgiliiana* series (*Oleo-Querco virgiliiana* sigmetum), typical of the clays of ex-cultivated fields.

**Distribution:** Sicani Mts. in Caltabellotta territory (southern slopes of Pizzo Telegrafo).

*ARTEMISIETOSUM ARBORESCENTIS* sub-  
bass. nova hoc loco (holotypus rel. 29, Tab. 2)

**Table:** 2, relevés 29-30.

**Differential species:** *Artemisia arborescens*, *Ruscus aculeatus*, *Anagyris foetida*.

**Substrate:** Quartzarenitic blocks.

**Bioclimate:** Upper mesomediterranean lower subumid.

**Syndinamism:** Microwoods 3-4 m high, established in the rocky clefts of large quartzarenitic blocks, in predominantly southern facing stations. They constitute the most advanced aspects of an edapho-xerophilous series, put in catenal contact with: a) rupicolous microgeoseries; b) *Teucrio siculi-Querco ilicis* holm oak series, tied to cooler and more humid sandstone rocky areas; c) *Festuco heterophyllae-Querco congestae* sigmetum, typical of the clays of the Numidian flysch (Brullo et al., 2009).

**Distribution:** Nebrodi Mts. in Cesaro territory (Rocca Rapiti, Rocca Nadore, Contrada Mercadante and Castel di Bolo).

*RHAMNETOSUM ALATERNI* subass. nova hoc loco (holotypus rel. 36, Tab. 2)

**Table:** 2, rel. 31-36.

**Differential species:** *Rhamnus alaternus*, *Phillyrea latifolia*.

**Substrate:** More or less fractured lava flows and outcrops.

**Bioclimate:** Upper thermomediterranean and mesomediterranean, with upper dry-upper subumid ombrotype.

**Syndinamism:** Microwoods 4-6 m high, established among the cracks of lava rocks, facing south/ southwest, in catenal contact with: a) *Celtido-Querco virginiana* sigmetum, typical of lava soils predominantly occupied by pistachio crops with *Pistacia vera*; b) *Festuco heterophyllae-Querco congestae* sigmetum, which substitutes the previous one at altitudes higher than 800 m a.s.l.; c) the *Teucrio siculi-Querco ilicis* series, tied to cooler and more humid lava rocky substrates (Brullo et al., 2009).

**Distribution:** southern-western and western slopes of Mount Etna.

## Syntaxonomy

Under the syntaxonomical aspect, the described *Celtis aetnensis* coenoses are referred to the alliance *Oleo-Ceratonion* (order *Pistacio-Rhamnetalia alaterni*, class *Quercetea ilicis*), according to the scheme reported at the end of the text.

## Concluding remarks

A synoptic comparison among the *Celtis tournefortii* subsp. *aetnensis* coenoses is reported in Tab. 3. Microwoods dominated by *Celtis tournefortii* subsp. *aetnensis* subject of this paper are scattered throughout the Sicilian range of the species, where they form impenetrable communities, sometimes even extended, denoting the important pioneer role of this entity in

Tab. 3 - Simplified synoptic table (sporadic species are not reported) of the *Celtis tournefortii* subsp. *aetnensis* communities relative to Tab. 2 [*Pistacio terebinthi-Celtidetum aetnensis typicum* subass. nova (1a), *phlomidetosum fruticosae* subass. nova (1b), *artemisietsom arborescentis* subass. nova (1c) and *rhamnetosum alaterni* subass. nova (1d)] and of the other coenoses with the presence of the species already reported for Sicily by other authors: 2 (Marcenò et al., 2002; Tab. 1, ril. 12 and 16, *Oleo-Euphorbiatum dendroidis* subass. *celtidetosum tournefortii*); 3 (Poli et al., 1981: *Celtido-Quercetum ilicis* n.n.); 4 (Brullo & Marcenò, 1985: Tab. 4, *Celtido aetnensis-Quercetum virginiana*).

the colonization of detrital substrates. The most expressive nuclei were found on the carbonate slopes of Pizzo Telegrafo, in the southern part of the Sicani Mts., where they represent the most advanced forest aspects of an edapho-xerophilous series, located on detrital coverages, present along the karst depressions of the mountains, on cones at the base of the slopes or at the bottom of the most xeric canyons.

In the other phytocoenotic types hitherto described in Sicily, *Celtis tournefortii* subsp. *aetnensis* has been instead considered as gregarious element in the following vegetation aspects: 1) *Euphorbia dendroides* maquis [*Oleo-Euphorbietum dendroidis* Trinajstić (1973) 1984 subass. *celtidetosum tournefortii* Marcenò *et al.* 2002; Marcenò *et al.*, 1995, 2002]; 2) *Quercus ilex* woods (*Celtido-Quercetum ilicis* n.n.; Poli *et*

*al.*, 1973, 1981); 3) *Quercus virgiliiana* woods (*Celtido aetnensis-Quercetum virgiliiana* Brullo & Marcenò, 1985; Brullo *et al.*, 2009).

However, these phytocoenoses, dominated by other species, are tied to the *Celtis tournefortii* subsp. *aetnensis* microwoods described by us. Indeed, the first two are also located on rocky outcrops placed in castral contact with the aforesited microwoods (*Euphorbia dendroides* maquis in the thermomediterranean; *Quercus ilex* woods in the mesomediterranean), whereas the *Celtido aetnensis-Quercetum virgiliiana* (Brullo & Marcenò, 1985) is an oak community where the species at issue is in any case relegated on small rocky surfaces, placed within volcanic Andosols, quite spread on the western side of Mt. Etna.
