The *Rhamnetalia fallacis* P. Fukarek 1969 in the eastern Alps, the Dinarides and the Apennines

E. Biondi, M. Allegrezza

Department of Agricultural, Food and Environmental Sciences, Marche Polytechnic University, I-60131 Ancona, Italy.

Abstract

The present contribution was designed to deepen the knowledge of the Italian forest vegetation through its connection with the dynamic, pre-forest and mantle aspects relating to *Oreoherzogia fallax* (=*Rhamnus alpina* L. subsp. *fallax* (Boiss.) Maire et Petitm., = *Rhamnus fallax* Boiss.), a south-eastern European orophyte of the south-eastern Alps, the Balkan peninsula and the Apennines. Considering the quality of the historical relationships between the Italian flora and vegetation and that of the Balkan peninsula, the study investigated in detail the vegetation of the order *Rhamnetalia fallacis* P. Fukarek 1969 indicated for the Balkan peninsula. The results of this study of the pre-forest vegetation of the beech forests of the association *Polysticho aculeati-Fagetum sylvaticae* subass. *taxetosum baccatae* of Campo Imperatore plateau allowed the identification of the new association *Taxo baccatae-Juniperetum nanae*, which is proposed as *typus* of the new Apennine alliance *Junipero nanae-Oreoherzogion fallacis*, vicariant for the Apennines of the alliance *Lonicero-Rhamnion fallacis* of a Balkan distribution. The new alliance *Junipero nanae-Oreoherzogion fallacis* is referred to the order *Rhamnetalia fallacis* and the class *Rhamno catharticae-Prunetea spinosae*.

Key words: Apennines, *Rhamnetalia fallacis*, *Rhamno-Prunetea*, syntaxonomy.

Introduction

With the aim of completing the Prodrome of Italian Vegetation (Biondi *et al.*, 2014), this contribution aims to deepen the knowledge of the Italian forest vegetation through its connection with the dynamical, pre-forest and mantle aspects relating to *Oreoherzogia fallax* (Boiss.) W. Vent (=*Rhamnus alpina* L. subsp. *fallax* (Boiss.) Maire & Petitm., = *Rhamnus fallax* Boiss.).

Oreoherzogia fallax is a south-eastern European montane shrub that is distributed through the south-eastern Alps (i.e., Julian Alps, Kamnik-Savinja Alps/Steiner Alps, Karavanke Mountains/ Karawanken), the Dinaric and Balkan Mountains, and the Apennine peninsula (Aeschimann *et al.*, 2004). Its distribution in Italy relates to the Apennines south of the Po Valley, down to Pollino.

In the Apennines, *Oreoherzogia fallax* is present in the supratemperate thermotype, with penetration into lower subalpine, on limestone substrates outcropping as blocks and/or as layers of debris with clasts of varying sizes. For the supratemperate thermotype, it is common in the pre-forest ecotonal shrub vegetation of beech forests (Biondi *et al.*, 1999, 2004; Allegrezza, 2003; Allegrezza *et al.*, 2013). Under conditions of hydrogeological instability, *Oreoherzogia fallax* can also be found (although often at low coverage) in *Juniperus communis* subsp. *nana* communities (Stanisci, 1997) and in *Juniperus communis* subsp. *nana* and *Juniperus communis* subsp. *hemisphaerica* communities

(Allegrezza *et al.*, 2013, 2016), referred to the alliance *Daphno oleoidis-Juniperion alpinae*.

Although sometimes without definitive attribution, the pre-forest communities with a dominance of *Oreoherzogia fallax* described in the literature for the Apennines (Biondi *et al.*, 1999, 2004; Allegrezza, 2003) were included in the alliance *Berberidion*, sub-alliance *Berberidenion* (Poldini, 2002; Cutini *et al.*, 2002), within the class *Rhamno catharticae-Prunetea spinosae*. The presence of a vicariant syntaxon for the Apennines, the alliance *Lonicero-Rhamnion fallacis* of the order *Rhamnetalia fallacis* described for the central Dinarids (Fukarek, 1969), has indeed been indicated repeatedly in several syntaxonomy studies (e.g., Stanisci, 1997; Biondi *et al.*, 1999; Poldini *et al.*, 2002).

Considering the quality of the historical relationships between the Italian flora and vegetation and that of the Balkan peninsula, it was decided to carry out a more detailed study of the vegetation of the order *Rhamnetalia fallacis* P. Fukarek 1969. In the European Prodrome (Mucina *et al.*, 2016), this order was placed in the class *Betulo carpaticae-Alnetea viridis* Rejmánek ex Boeuf, Theurillat, Willner, Mucina and Simler by Boeuf *et al.* (2014). In the same study, this class was defined as follows: "Subalpine and subarctic herb-rich alder and willow scrub and krummholz of the Alps, the Carpathians, the Hercynicum, the Balkans, the Caucasus, northern Europe and Greenland". The order *Rhamnetalia fallacis* P. Fukarek 1969 was instead defined as: "Relict deciduous scrub in the mountains and subalpine belts

of the southern Alps, Dinarides and Apennines". This order lists two alliances: *Seslerio calcariae-Rhamnion fallacis* Dakskobler *et al.* 2013 ("Relict deciduous scrub in the mountains and subalpine belts of the southern Alps"); and *Lonicero-Rhamnion fallacis* P. Fukarek 1969 ("Relict deciduous scrub in the supramontane and subalpine belts of the Dinarides and Apennines"), the alliance *typus* of the order *Rhamnetalia fallacis*. Therefore, although there have not been any clear references in the Apennines to this syntaxon, it is evident that according to the European Prodrome, the second of these two alliances refers to the vegetation of *Oreohenzogia fallax* in the Apennines.

The study area

The territory investigated here is located in the south-western sector of the Campo Imperatore plateau of Gran Sasso in Italy, at altitudes between 1,460 and 1,650 m a.s.l. (Fig. 1a). This plateau is at the foot of the main limestone mountains of the Gran Sasso d'Italia group, which were strongly shaped by glaciation and morphogenetic phenomena, mainly including karst, snow, wind and water (Calandra, 1999).

The plant landscape is represented by grasslands and limited beech woods that occupy the deep pockets of soil on the limestone outcrops. In the current phase of partial abandonment of the grasslands, these woods tend to recover their potential space, through mantle and pre-forest formations that favour their enlargement.

The bioclimatic classification according to Rivas-Martínez *et al.* (2011) indicates a temperate macroclimate, an oceanic bioclimate, and an upper supratemperate thermotype and humid ombrotype (Baldoni, 1999; Pesaresi *et al.*, 2014, 2017). Specifically for the thermo-pluvial station of Castel del Monte (1,325 m

a.s.l.), which is adjacent to the study area, the bioclimatic classification according to Rivas-Martínez *et al.* (2008) indicates a sub-Mediterranean variant at the level of a temperate macroclimate (Fig. 2).

Materials and methods

The study of the vegetation was carried out following the phytosociological methods of the Zurich-Montpellierian school, as successively integrated (e.g., Rivas-Martínez, 2005; Biondi, 2011; Blasi *et al.*, 2011). The nomenclature of the species follows Bartolucci *et al.* (2018), with the exception of the genus *Juniperus*, which follows Flora Europaea (Tutin *et al.*, 1964). The biological forms of the species follow Flora d'Italia (Pignatti, 1982), while the chorology of the species follows Flora Alpina (Aeschimann, 2004).

The comparisons with the literature data made use of the synthetic columns related to the syntaxa with a dominance of *Oreohenzogia fallax* described for the Apennines (Biondi *et al.*, 1999, 2004; Allegrezza, 2003), the south-eastern Alps (Dakskobler *et al.*, 2013) and the north-western (Dakskobler *et al.*, 2013) and central (Fukarek, 1969) Dinarids.

The numerical comparations were made using the VEGAN community ecology package for R (Oksanen *et al.*, 2012). The columns of the synthetic table compiled were compared using hierarchical classification and ordination, as Principal Coordinates Analysis (PCoA).

The phytosociological nomenclature follows the rules of the International Code of Phytosociological Nomenclature (Weber *et al.*, 2000). For the definition of the syntaxa, the Prodrome of Italian Vegetation was followed (Biondi *et al.*, 2014; see the specific interactive site of the Italian Botanical Society: <http://www.prodromo-vegetazione-italia.org/>), with reference to

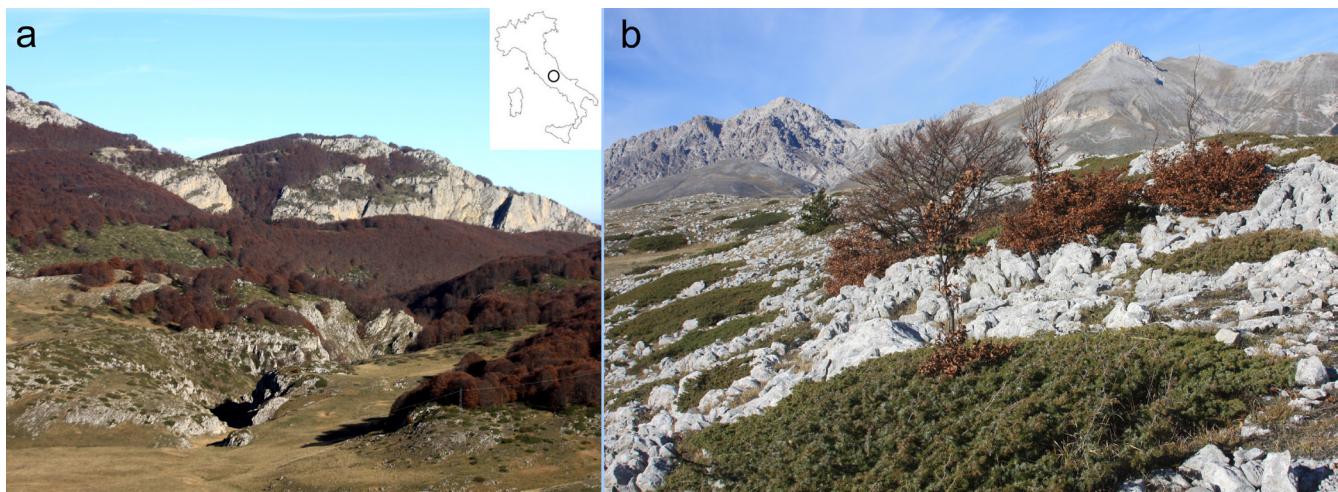

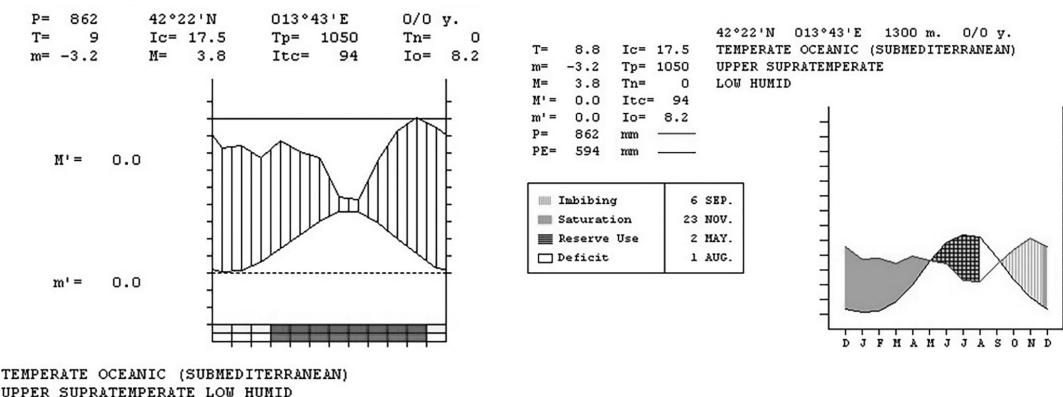

Fig. 1 - a) Beech woods in the southern sector of the Campo Imperatore plateau (Gran Sasso d'Italia) where the vegetation mantles in contact with the beech forest have been studied; b) the role of the *Juniperus communis* subsp. *nana* in the beech forest dynamic processes.

Results and discussion

Pre-forest vegetation in the study area

TAXO BACCATAE-JUNIPERETUM NANAЕ ass. nova hoc loco (holotypus: rel. 4 of Tab. 1)

In the ecotonal positions of the beech forests of the association *Polysticho aculeati-Fagetum sylvaticae*, subass. *taxetosum baccatae* described for the Campo Imperatore plateau (Biondi *et al.*, 1999) there is high-shrub pre-forest vegetation with a maximum height of 2-3 m. This is characterised by the constant presence of *Taxus baccata*, *Oreoherzogia fallax*, *Prunus mahaleb*, *Amelanchier ovalis*, *Sorbus aria*, *Rosa canina*, *Fagus sylvatica* and *Rubus idaeus* (Tab. 1). These are inserted on a carpet of *Juniperus communis* subsp. *nana* that is sometimes interpenetrated by *Juniperus communis* subsp. *hemisphaerica*, and by herbaceous edge species (e.g., *Digitalis ferruginea*, *Siler montanum* subsp. *siculum*) and grassland species (e.g., *Bromopsis erecta*, *Euphorbia cyparissias*). *Fagus sylvatica* is always present both in the shrub layer and with sparse trees that are 10-12 m in height.

Juniperus communis subsp. *hemisphaerica* is of particular interest here, and was previously reported for the territory in question by Biondi *et al.* (1999). It is a polyhormous plant that can reach a height of over 2 m and is found in the north-western mountainous areas of Africa (i.e., Morocco, Algeria), in the continental areas of the Iberian peninsula (i.e., Spain, Portugal), in some of the western and central Mediterranean islands (e.g., Balearic, Corsica, Sardinia, Sicily), and in the south of the Balkan peninsula (i.e., Albania, Macedonia, Greece, Bulgaria) (Jalas & Souminen, 1972). In Italy, in addition to the two major islands indicated, it is also found in the mountainous areas of the Apennines, reaching its northern limit of distribution in the northern part of the Sibillini Mountains (central Italy) (Allegrezza *et al.*, 2013) and in the southern area of the Italian peninsula, in Aspromonte (Brullo *et al.*, 2001).

The processing of the data in Tab. 1 and the comparison with the literature data (Tab. 2) allowed the proposal of the new association *Taxo baccatae-Juniperetum nanae ass. nova hoc loco (holotypus rel. 4 of Tab. 1)*, for which the characteristic and differential species are considered to be: *Juniperus communis* L. subsp. *nana* Syme; *J. communis* L. subsp. *hemisphaerica* (J. Presl et C. Presl) Nyman; *Taxus baccata* L.; *Digitalis ferruginea* L.; and *Amelanchier ovalis* Medik. subsp. *ovalis*.

At a class syntaxonomic level, this vegetation belongs to the class *Rhamno catharticae-Prunetea spinosae* through both the diversity and cover of species of the syntaxon: e.g., *Prunus mahaleb*, *Amelanchier ovalis*, *Rosa canina*, *R. spinosissima*, *Rubus idaeus*, and *Juniperus communis* subsp. *communis*. The assignment at the order and alliance levels is more complex.

The proposal for a new Apennine alliance for the *Oreoherzogia fallax* vegetation

The dendrogram obtained from the classification of the groups of the relevés (Fig. 3) related to the different syntaxa described in the literature (Tab. 2) separates three groups of relevés that correspond to three distinct biogeographical contexts: Alpine (cluster Ia, except for the n. 13, *Lunario redivivae-Rhamnetum fallacis* association, described for NW Dinarids), Dinaric (cluster Ib), and Apenninic (cluster Ic). The

PCoA ordination (Fig. 3) confirms the separation of the groups obtained with the classification and the trend of floristic variations from the typically alpine floristic context expressed by the alliance *Seslerio calcariae-Rhamnion fallacis*, to the Dinaric context of the alliance *Lonicero-Rhamnion fallacis, typus* of the order *Rhamnetalia fallacis*, to the Apenninic context, for which (also on the basis of the elaboration of the data of Tab. 2) the new alliance *Junipero nanae-Oreohertzogion fallacis* is proposed, of which the new association *Taxo baccatae-Juniperetum nanae* represents the *typus*.

JUNIPERO NANAЕ-OREOHERZOGION FALLACIS
all. nova *hoc loco*
(holotypus: *Taxo baccatae-Juniperetum nanae* ass.
nova *hoc loco*)

The new alliance refers to the secondary shrubby communities of *Oreohertzogia fallax* that develop on calcareous outcropping substrates and lithosols of the Apennine reliefs from lower to upper supratemperate thermotype, in dynamic connection with beech woods of the alliances *Aremonio-Fagion sylvaticae* and *Geranio striati-Fagion sylvaticae* in the more rocky aspects. The abundant and frequent species of the new syntaxon are: *Oreohertzogia fallax*, *Siler montanum* subsp. *siculum*, *Sorbus aria*, *Cotoneaster pyrenaicus*, *Fagus sylvatica*, and *Prunus mahaleb*.

The diagnostic species of the proposed new alliance are considered to be: *Oreohertzogia fallax*, *Siler montanum* subsp. *siculum*, *Rubus idaeus*, *Daphne mezereum*, *Amelanchier ovalis*, *Juniperus communis* subsp. *hemisphaerica*, *J. communis* subsp. *nana*, *Rhamnus saxatilis*, *Prunus mahaleb*, and *Centaurea triumfettii*.

At its altitude limit of distribution, the pre-forest communities of the new alliance *Junipero nanae-Oreohertzogion fallacis* is in chain contact with *Juniperus communis* subsp. *nana* communities, which are highlighted for the most rocky aspects by the ingress of shrub species of the alliance *Daphno oleoidis-Juniperion alpinæ*. Under conditions of severe hydrogeological instability, and following vegetative regression, these communities can sometimes also assume the role of permanent populations of a sub-prime nature.

The new alliance *Junipero nanae-Oreohertzogion fallacis* is referred to the order *Rhamnetalia fallacis* and represents the Apennine vicariant of the alliance *Lonicero-Rhamnion fallacis* Fukarek 1969 of the Dinarids (Mucina et al., 2016). The Apennine coenoses with a dominance of *Oreohertzogia fallax* at its western limit of distribution are distinguished by the purely mountainous and sometimes sub-Mediterranean character that is linked to the same area of *Oreohertzogia fallax* in the Apennines of its central-southern sector. It is interesting to note, however, that despite the different floristic compositions of the different biogeographical

and bioclimatic contexts, the physiognomy and ecology of these communities described in the literature are similar.

At the class level, the order *Rhamnetalia fallacis* is here classified in the class *Rhamno catharticae-Prunetea spinosae*, which is defined according to the European Prodrome as "Scrub and mantle vegetation seral or marginal to broad-leaved forests in the nemoral zone and the submediterranean regions of Europe" according to the shrub physiognomy of the communities described and the prevailing syndynamic significance, with the deciduous woods highlighted in the different syntaxa described in the literature and used in the comparisons for Tab. 2 (Fukarek, 1969; Biondi et al., 1999, 2004; Allegrezza, 2003; Dakskobler et al., 2013). Our proposal is not in agreement with recent interpretations that include the order *Rhamnetalia fallacis* Fukarek 1969, for which the alliance *Lonicero-Rhamnion fallacis* represents the *typus* (Dakskobler et al., 2013), in the class *Querco-Fagetea* (Trinajstić, 2008; Dakskobler et al., 2013) or in the class *Betulo carpaticae-Alnetea viridis* (Mucina et al., 2016; Škvorc et al., 2017).

In the original proposal, Fukarek (1969) followed the suggestion of Horvat (1962), and proposed the order *Rhamnetalia fallacis* Fukarek 1969 and the alliance *Lonicero-Rhamnion fallacis* for the Balkans, with the vicariant of the order *Prunetalia spinosae* and the alliance *Berberidion* with a contingent of differential species, such as: *Oreohertzogia fallax*; *Berberis illyrica*; *Lonicera alpigena* subsp. *glandulifera*; *Ribes alpinum* subsp. *pallidigemmum*; *Rosae* div. sp. *illyricae*; *Salix appendiculata*; *Lonicera glutinosa*; and *Viburnum maculatum*. These shrubby coenoses with a dominance of *Oreohertzogia fallax* were classified by Trinajstić (2008) into the class *Querco-Fagetea*, in terms of the floristic affinity with the beech woods. The present proposal of classification of the order *Rhamnetalia fallacis* into the class *Rhamno catharticae-Prunetea spinosae* is based not only on the shrub-like physiognomy, but also on the community syndynamics that are evident also in the floristic composition of the original association *Cynanco vincetoxicici-Rhamnetum fallacis* P. Fukarek & Stefanović 1958 (in Fukarek & Stefanović, 1958: 139) indicated as association *typus* of the alliance (Dakskobler et al., 2013), and therefore of the order, for the presence of common species in the pre-forest communities that are dynamically linked to the high-mountain edafoxerophilous beech woods, like *Sorbus aria*, *Cotoneaster pyrenaicus*, *Vincetoxicum hirundinaria*.

For the classification of the order *Rhamnetalia fallacis* into the class *Betulo carpaticae-Alnetea viridis* ("Subalpine and subarctic herb-rich alder and willow scrub and krummholz of the Alps, the Carpathians, the Hercynicum, the Balkans, the Caucasus, northern

Europe and Greenland") proposed by Mucina *et al.* (2016) and also adopted by the current Prodromo of Croatia (Škvorc *et al.*, 2017), this would not appear feasible at present on the basis of the published data, as also indicated by Dakskobler *et al.* (2013), because with the exception of *Salix appendiculata* (with low presence and cover value), the characteristic species of the class are absent.

Future phytosociological studies on *Oreohenzogia fallax* vegetation in the southern Balkans (e.g., Macedonia) will help to complete the syntaxonomic scheme of the order *Rhamnetalia fallacis* and to deepen the ecology of *Oreohenzogia fallax* at its southern limit of distribution in Europe.

Based on the recent classification of the EUNIS habitats (Schaminée *et al.*, 2014), the alliance *Lonicero-Rhamnion fallacis* Fukarek 1969 is part of the habitat code S2-5 of "Subalpine deciduous scrub", which is defined as: "Low scrub, including krummholz, dominated with various deciduous trees and shrubs, on moist but free-draining, sometimes quite fertile, soils on high mountain slopes throughout Europe, often with long snow-lie and prone to natural disturbance due to avalanches and scree slides, after which it is well able to recover and recolonise. The associated flora can be rich in tall mountain herbs. It can also be found as a secondary succession stage in abandoned subalpine pastures and meadows". Among the diagnostic species indicated for this habitat (i.e., *Alnus viridis*, *Viola biflora*, *Peucedanum ostruthium*, *Adenostyles alliariae*, *Saxifraga rotundifolia*, *Salix waldsteiniana*, *Salix appendiculata*, *Rumex alpestris*, *Salix helvetica*, *Geranium sylvaticum*, *Athyrium distentifolium*, *Achillea macrophylla*, *Aconitum napellus*, *Chaerophyllum villarsii*, Alpine grasshopper, *Rhododendron hirsutum*, *Polystichum lonchitis*, *Epilobium alpestre*, *Veratrum album*, *Cymbalaria hepaticifolia*), only *Salix appendiculata* is present in the syntaxa of

the Dinaric alliance. *Rhamnus alpinus* is indeed only indicated among the dominant species, and does not assume the diagnostic value of the habitat. The reference to the habitat code S2-5 "Subalpine deciduous scrub" might be more consistent with the alliance *Seslerio calcariae-Rhamnion fallacis* Dakskobler *et al.* 2013 that was described for the south-eastern Alps through the presence in the floristic composition of some of the diagnostic species indicated for the habitat in question (Tab. 2). Finally, the new Apennine alliance *Junipero nanae-Oreohenzogion fallacis* described here does not fall within the S2-5 "Subalpine deciduous scrub" habitat due to the absence of the indicated diagnostic species, which reflects the typically mountain and high-mountain position of the phytocoenosis described.

Conclusions

This study has made it possible to deepen the knowledge of the pre-forest and mantle vegetation relating to *Oreohenzogia fallax* (=*Rhamnus alpina* L. subsp. *fallax* (Boiss.) Maire et Petimg.), a south-eastern orophyte that is distributed in the south-eastern Alps, the Balkan peninsula and the Apennines. These data on the pre-forest vegetation of the beech forests of the association *Polysticho aculeati-Fagetum sylvaticae* subass. *taxetosum baccatae* present on the Campo Imperatore plateau has allowed the identification of the new association *Taxo baccatae-Juniperetum nanae* that is proposed as *typus* of the new Apennine alliance *Junipero nanae-Oreohenzogion fallacis*, vicariant for the Apennines of the alliance *Lonicero-Rhamnion fallacis* with a Balkan distribution. The new alliance *Junipero nanae-Oreohenzogion fallacis* is referred to the order *Rhamnetalia fallacis* and the class *Rhamno catharticae-Prunetea spinosae*.
